

File permissions in Linux

Project description

Linux commands allow you to communicate with the OS through the command line, these commands are instructions telling a computer to execute a task.

Check file and directory details

`pwd` prints the current directory onto the screen, the output tells you which output you are currently in. `ls` displays the names of files and directories in the current working directory.

Describe the permissions string

Can read, write and execute files and directories. File permissions are represented with a ten character string (drwxrwxrwx). (r) stands for read, (w) stands for write and (x) stands execute permissions. The first character can be either a file represented as (-) or directory as (d), followed by three characters which represent the user's permissions. Then, the next three characters represent the group's permissions and the final three characters represent the other's permissions.

Change file permissions

Changing permissions involves adding options to the `ls` command. `ls -l` displays permissions to files and directories. `chmod` command is used to change permissions on files and directories.

Change file permissions on a hidden file

`ls -a` displays hidden files. `ls -la` displays both files and directories and hidden files.

Change directory permissions

Files and directories belong to researcher2. Currently in /home/researcher2/projects. To change directory permissions use `chmod u+r, u+w projects`
